9. Python Exercises: writing files

Make a program that merge two ordered input files and write them into an ordered output file. How-to:

1. Ask the user for the name of two input files. If some of them don't exist, display an error message and exit.
2. Ask the user for the name the output file. If it exists, display a warning message and ask the user for overwriting the file or exit.
3. Using a while loop and the method readline(), read the input files line by line and write them into the output file in such a way that it is ordered too. Do not use any kind of array.
